Customer	Tove Mariegaard Pedersen
Customer ID	DA00206-23
Project	Regenerativt landbrug til videreudvikling af den økologiske planteproduktion
Sample Type	Soil
Number of samples	14 samples
Type of data	Shotgun metagenomic sequencing

Processing of the Shotgun metagenomic sequencing data through quality control and microbiome profiling across the 14 samples resulted in the detection of microorganisms (see report 2 on taxonomy) and profiling of the functional capacity of the microbes. The software HUMAnN3 was used to profile the functional capacity in terms of MetaCyc pathways and UniRef50 gene families. The latter was regrouped to Gene Ontology (GO) and KEGG Orthology (KO) terms. The functional profiling is described in detail in “**Report 1: Sequencing and Data Processing Report**” and the different databases used for the grouping of the functions is described below.

- **MetaCyc Metabolic Pathways:** Metacyc is a curated database of metabolic pathways across all domains of life. It only includes pathways that have been experimentally studied (in contrast, many other databases also contain computationally predicted pathways). MetaCyc contains 2937 pathways from 3295 different organisms. Website: <https://metacyc.org/> (<https://metacyc.org/>)
- **KO:** The KO database is a database of functions grouped by orthology (i.e. groups of genes with the same function across different organisms). The KO terms link pathways and functions and thereby, pathways can be identified from the KO terms. Website: <https://www.genome.jp/kegg/ko.html> (<https://www.genome.jp/kegg/ko.html>)
- **GO:** The GO database contains functional information of genes. As compared to KO, GO is not structured around pathways but instead, the so-called ontologies (a specific way of structuring functional information and functional relationships). Each gene is associated with a GO term describing the function of the gene. Website: <http://geneontology.org/docs/ontology-documentation/> (<http://geneontology.org/docs/ontology-documentation/>)

These databases all have different strengths and limitations and therefore, to be as exhaustive as possible, we use all three databases for the regrouping of the UniRef50 gene families.

Functional capacity versus functional activity

There are two types of data we can use for profiling of the functional capacity of the microbes; shotgun metagenomic sequencing and metatranscriptomics, where the former is sequencing of the DNA and the latter is sequencing of RNA. There are some important differences between the information we obtain with these two types of data. With sequencing of DNA we obtain sequences from the whole genome (both coding and non-coding sections) whereas with sequencing of RNA we only obtain sequences from the coding part of the genome. Furthermore, when we investigate the DNA we look at the functional capacity and we do not obtain information of the expression level of the genes. In contrast, with RNA sequencing we can analyse the functional activity, i.e. the expression level of the genes. For example, a gene can have a low relative abundance at DNA level but a high relative abundance at RNA level due to a high expression of the gene. These considerations are important to keep in mind when interpreting the data shown in this report. In this report, we look at the functional capacity as we have performed DNA sequencing.

Most abundant functional terms/pathways

This section lists the most abundant functional terms/pathways detected in your data for each of the described databases. This section is meant to give you a first impression of the format of the functional data, the types of terms and pathways detected, and how they are named. To evaluate further, you can try to google the terms or look them up in the individual databases using the links given above in order to get a better understanding of their interpretation and usage.

The tables show the most abundant functional terms/pathways. These will often be the household functions and are often not the most interesting for you to study and evaluate further. Therefore, based on your question of interest, we also highlight some functional terms/pathways that may be of special interest in your project. These can be seen in the tables in the section “**Functional terms/pathways of interest**”.

The values in all of the following tables range from 1-100, with the exception of some values that sum to more than 100 due to the structure of the databases (i.e. one gene is found in more than one term). Due to the high fraction of unmapped reads and the high number of functional terms/pathways, the numbers are quite small.

Most abundant MetaCyc pathways

	Min.	1st Qu.	Median	Mean	3rd Qu.	Max.
UNMAPPED	5.51E+01	5.66E+01	5.68E+01	5.68E+01	5.74E+01	5.80E+01

PWY-6125: superpathway of guanosine nucleotides de novo biosynthesis II	1.91E-02	1.96E-02	1.99E-02	2.01E-02	2.04E-02	2.13E-02

Table 1: Summary statistics for top 20 most abundant MetaCyc pathways. Summary statistics were computed for all pathways and the 20 most abundant were selected based on the median relative abundance across the samples.

The data set contains 618 different pathways, not considering the UNMAPPED and UNINTEGRATED.

- The UNMAPPED row contains information on the fraction of reads that did not map to a gene in the reference database
- The UNINTEGRATED row contains information on the fraction of reads that did map to a gene in the reference database, but where the gene is not contributing to a pathway in the used pathway database.

The UNMAPPED and UNINTEGRATED rows allow for evaluation of the fraction of data that does not contribute to the identified functions and therefore, is not used in further analysis. We do expect a fairly high number of UNINTEGRATED reads, as many known genes are not assigned to known pathways. Furthermore, for soil samples, a high percentage (>80%) of UNMAPPED reads is expected as the soil microbiome is very complex and not well-described in the reference databases.

Table 2: Summary statistics for top 20 most abundant KO terms. Summary statistics were computed for all KO terms and the 20 most abundant were selected based on the median relative abundance across the samples (KO terms assigned as “subunit ribosomal protein” were not included in the table as these are highly abundant and not that informative).

The data set contains 6542 different KO terms, not considering the UNMAPPED and UNGROUPED.

- The UNMAPPED row contains information on the fraction of reads that did not map to a gene in the reference database
- The UNGROUPED row contains information on the fraction of reads that did map to a gene in the reference database, but where the gene is not contributing to a pathway in the used pathway database.

The UNMAPPED and UNGROUPED rows allow for evaluation of the fraction of data that does not contribute to the identified functions and therefore, is not used in further analysis. We do expect a fairly high number of UNGROUPED reads, as many known genes are not part of a known KO term. Furthermore, for soil samples, a high percentage (>80%) of UNMAPPED reads is expected as the soil microbiome is very complex and not well-described in the reference databases.

Most abundant GO terms

The GO terms are split into three main categories:

- Biological process [BP]
- Molecular function [MF]
- Cellular component [CC]

Of these three categories we find the biological process most informative and thus, we selected the top 20 most abundant BP terms from the GO data set. For more information about the individual GO terms, we refer to the QuickGo homepage: <https://www.ebi.ac.uk/QuickGO/> (<https://www.ebi.ac.uk/QuickGO/>).

Table 3: Summary statistics for top 20 most abundant KO terms. Summary statistics were computed for all GO terms in the BP category and the 20 most abundant were selected based on the median relative abundance across the samples.

The data set contains 3640 different GO terms in the BP category, not considering the UNMAPPED and UNGROUPED.

- The UNMAPPED row contains information on the fraction of reads that did not map to a gene in the reference database
- The UNGROUPED row contains information on the fraction of reads that did map to a gene in the reference database, but where the gene is not contributing to a pathway in the used pathway database.

The UNMAPPED and UNGROUPED rows allow for evaluation of the fraction of data that does not contribute to the identified functions and therefore, is not used in further analysis. For soil samples, a high percentage (>80%) of UNMAPPED reads is expected as the soil microbiome is very complex and not well-described in the reference databases.

Functional terms of interest

To obtain an overview of functions of special interest in your project, we selected BP and GO terms related to the following functions: nitrogen metabolism, sulfur metabolism, methane metabolism, carbon fixation, symbiosis and photosynthesis. The selected functions are not exhaustive however, it provides a good overview of which aspects of the functional capacity that might be interesting to zoom in on.

Selected BP terms

To extract BP terms of special interest, we searched the BP terms using the following keywords: “nitrogen”, “nitrate”, “nitrite”, “nitrification”, “ammonium”, “ammonia”, “ammonification”, “urea”, “carbon”, “phosphorus”, “phosphate”, “methane”, “sulfate”, “sulfur”, “potassium”, “symbiotic”, “photosynthesis”, “respiration” and “starvation”. For more information about the individual GO terms, we refer to the QuickGo homepage: <https://www.ebi.ac.uk/QuickGO/> (<https://www.ebi.ac.uk/QuickGO/>).

Table 4: Summary statistics for GO terms of interest. Summary statistics were computed for the selected GO terms. The selection of GO terms was performed using the keywords found above the table.

Selected KO terms involved in Nitrogen metabolism

The GO terms in the above table are quite broad terms and thus, in order to investigate specific genes involved in nitrogen metabolism, we selected KOs in the KEEG modules found in “Nitrogen metabolism” at <https://www.genome.jp/brite/ko00002> (<https://www.genome.jp/brite/ko00002>). For some of the broad modules, we selected specific parts of the module and only included the relevant KOs. Thus, not all of the module names seen in the below boxplot correspond to a KEEG module name (instead, they are part of a larger KEEG module).

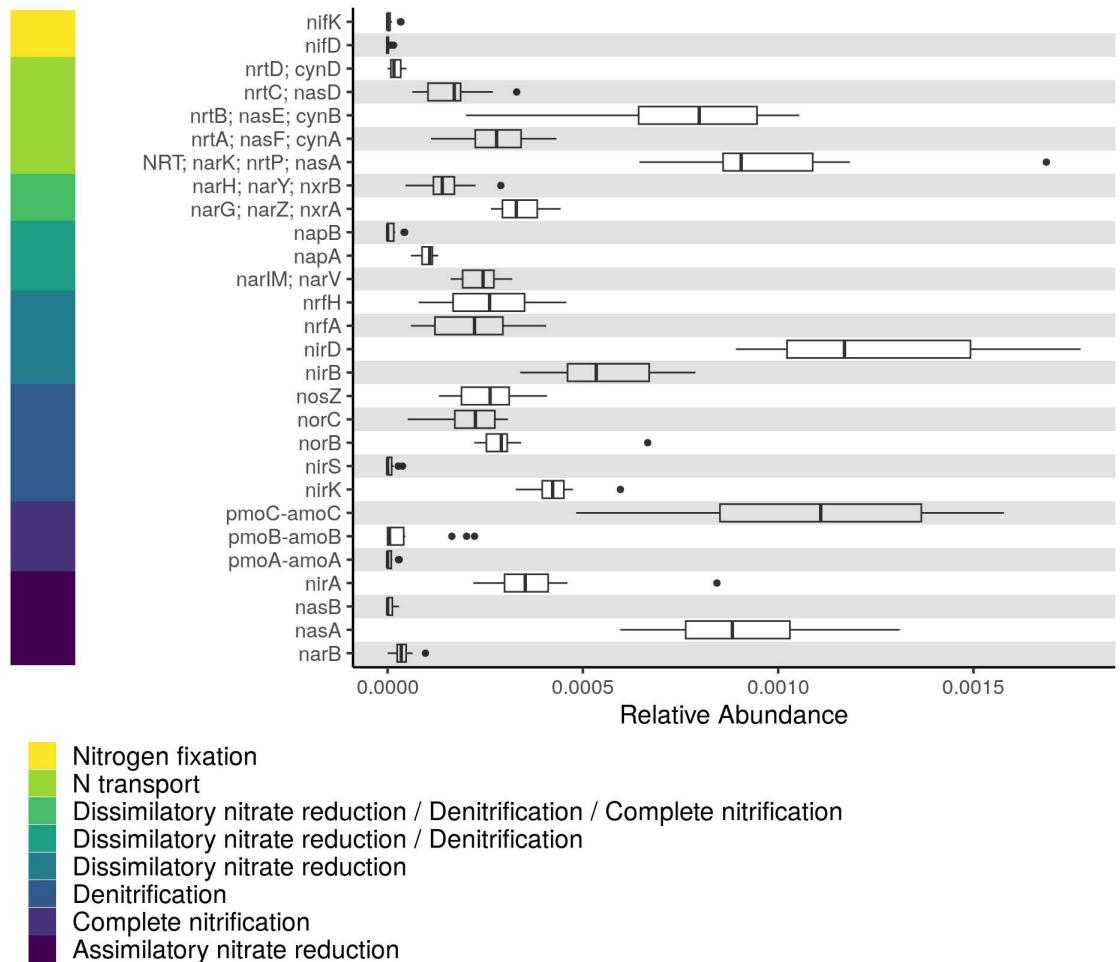

Figure 1: Boxplot of selected KO terms found in Nitrogen metabolism. The colored bar indicates which KEEG module each KO belongs to. Each row in the boxplot is one KO group (some groups have multiple names as seen in the figure). Furthermore, some KOs are found in several modules as indicated in the legend of the colored bar.

Selected KO terms involved in Sulfur metabolism

The GO terms are quite broad terms and thus, in order to investigate specific genes involved in Sulfur metabolism, we selected KOs in the KEEG modules found in “Sulfur metabolism” at <https://www.genome.jp/brite/ko00002> (<https://www.genome.jp/brite/ko00002>). For some of the broad modules, we selected specific parts of the module and only included the relevant KOs. Thus, not all of the module names seen in the below boxplot correspond to a KEEG module name (instead, they are part of a larger KEEG module).

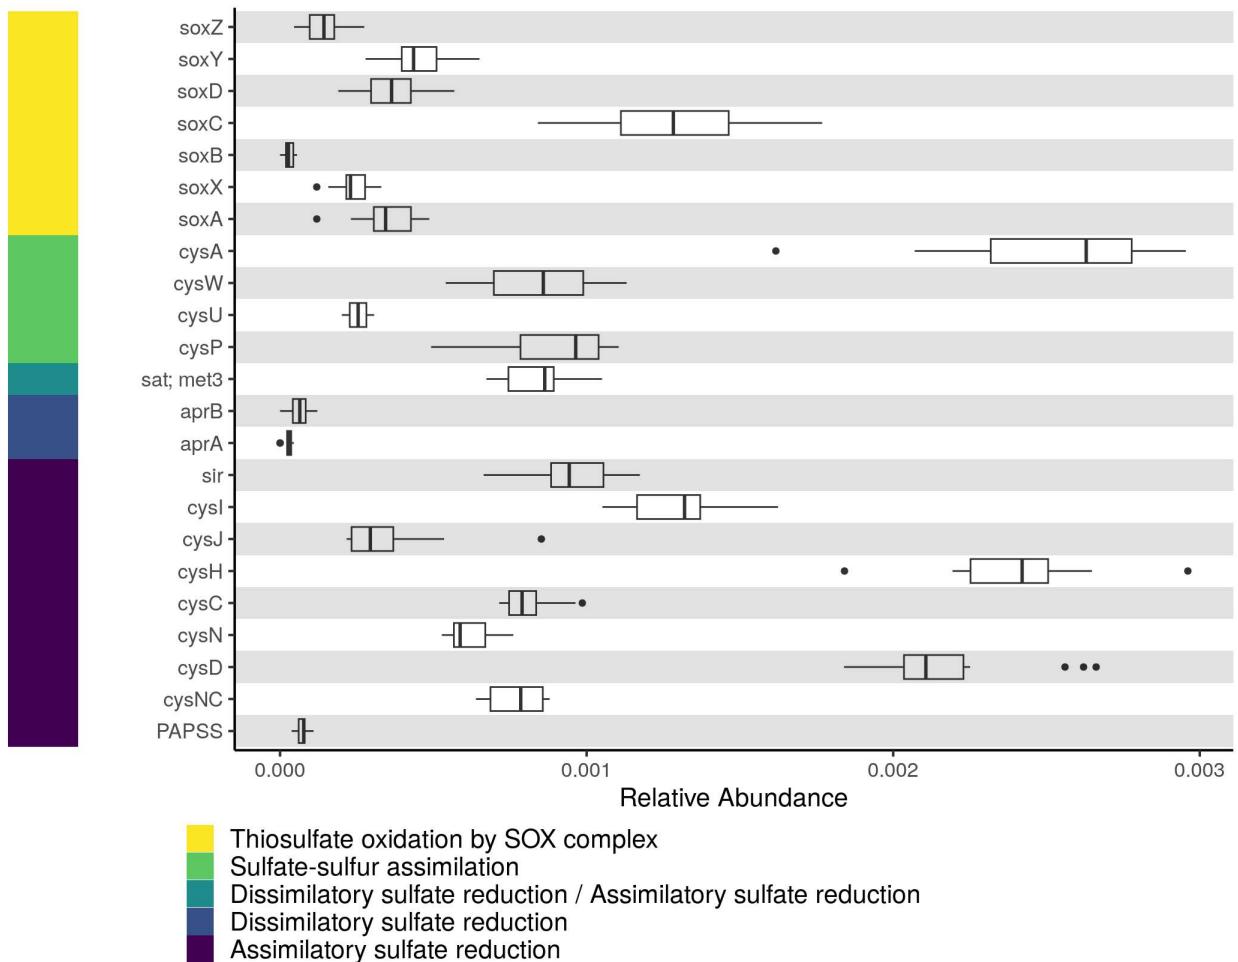

Figure 2: Boxplot Boxplot of selected KO terms found in Sulfur metabolism. The colored bar indicates which KEEG module each KO belongs to. Each row in the boxplot is one KO group (some groups have multiple names as seen in the figure). Furthermore, some KOs are found in several modules as indicated in the legend of the colored bar.

Selected KO terms involved in carbon metabolism

For the carbon metabolism, the KEGG modules are very broad and we therefore find it more interesting to zoom in on specific aspects of the carbon metabolism. Therefore, we selected KO terms based on a recent article (Kelly et al., 2021). The KOs were selected based on their Enzyme Commission Number (EC Number) and the included EC numbers were grouped by the type of compound they metabolize as seen in the article and in **figure 3**.
